(57) **ABSTRACT**

In a data transmission system such as a television service provider system, compensation value data corresponding to information lost during lossy compression of program content (which may or may not already be compressed prior to the lossy compression) may be sent to a customer along with the lossy-compressed content. At the customer end, the compensation value data may be used during decompression to provide higher quality content to the customer than would otherwise be experienced without access to the compensation values.

## TRANSMISSION OF COMPRESSED DATA STREAM WITH COMPENSATION VALUES

### CROSS-REFERENCE TO RELATED APPLICATIONS

The present application is a continuation of U.S. patent application Ser. No. 12/644,377, filed Dec. 22, 2009, entitled “Transmission of Compressed Data Stream with Compensation Values,” hereby incorporated by reference as to its entirety.

### BACKGROUND

Television service providers typically multiplex a large number of channels onto a single transport medium. The content for these channels is usually compressed into one or more Moving Picture Experts Group (MPEG) standard transport streams, with each channel being represented by a different program identifier (PID) contained in each data packet. Each transport stream is, in turn, modulated onto a respective carrier wave within a dedicated region of bandwidth around that carrier wave. Each region of bandwidth is sometimes referred to as a “QAM,” which also stands for “quadrature amplitude modulation,” because that is a typical carrier modulation technique used. In fact, the term QAM is variously used to refer to the carrier modulation technique, the region of bandwidth, and even equipment used to perform the modulation or otherwise process the modulated transport stream.

Each QAM bandwidth region typically has a fixed maximum bandwidth capacity and contains a subset group of the channels. For instance, a particular QAM bandwidth region may contain two or more high-definition channels per QAM bandwidth region, or ten to twenty standard definition channels. Regardless of how the channels, or PIDs, are divided amongst the QAM bandwidth regions, the total bandwidth of the channels carried on a QAM bandwidth region is not supposed to exceed the total fixed capacity of that QAM bandwidth region. However, the total bandwidth of a group of channels is difficult to determine, because the actual bandwidth needed by each channel can vary widely and unpredictably over time. Factors that affect the variability in bandwidth needed by a channel include, for instance, the amount of motion in a video scene or the number of quick cuts between scenes.

Therefore, while television service providers would like to maximize the number of channels on each QAM bandwidth region, they are limited somewhat by unpredictable variations in actual bandwidth used by the channels. If the actual bandwidth exceeds the QAM bandwidth region capacity, then the quality of the content may temporarily drop for all MPEG streams contained within the same QAM bandwidth region, resulting in artifacts such as blocking and freezing of video and distortion of audio. The provider can put fewer channels on each QAM bandwidth region to reduce the probability of exceeding QAM bandwidth region capacity. However, this is not ideal because a portion of bandwidth in that region will go unused most of the time. To deal with this problem, many providers implement an MPEG groumer, which further compresses the content for each channel on a QAM bandwidth region at times when the total bandwidth needed by the channels on that QAM bandwidth region would otherwise exceed the capacity of that bandwidth region. This additional compression (sometimes called “recompression”) is typically lossy, meaning that information is irreversibly removed from the transmitted data so that the data may be smaller. There-

2

fore, such recompression causes an inevitable drop in content quality as received by the customer/television viewer. While the recompression quality drop is expected to be smaller and more controllable than the quality drop that would occur by simply letting the actual bandwidth exceed the capacity of the QAM bandwidth region, such a quality drop is still undesirable.

### SUMMARY

Techniques are discussed that may reduce or even eliminate the quality drop experienced by the viewer when lossy compression (e.g., initial compression and/or subsequent recompression) is performed. In general, data representing compensation values corresponding to the information lost during compression may be sent to the customer along with the compressed content. At the customer end, the compensation values may be used during decompression to provide higher quality content to the customer than would otherwise be experienced without access to the compensation values. By having access to the compensation values, the customer receiver equipment may therefore partially or fully reverse the compression performed by the service provider’s MPEG groumer.

To avoid utilizing bandwidth in a QAM bandwidth region in which the content is already being compressed (referred to herein as a “content QAM”), the compensation values may be transmitted utilizing bandwidth outside that content QAM. For example, the compensation values may be provided on a QAM bandwidth region (referred to herein as a “compensation QAM”) different from the content QAM on which the associated compressed content is transmitted. Thus, the information previously lost to compression may still be received by the customer without requiring any additional bandwidth in the content QAM. In addition, multiple content QAMs may share the same compensation QAM and/or utilize more than one compensation QAM.

Thus, for example, some aspects are directed to a method, comprising: compressing data to generate compressed data; determining compensation value data representing information lost during said compression; transmitting at least a portion of the compressed data in a first frequency band; and transmitting the compensation value data in a second frequency band different from the first frequency band.

Further illustrative aspects are directed to a system, comprising a compressor and a transmitter. The compressor may be configured to compress data to generate compressed data, and determine compensation value data representing information lost during compression. The transmitter may be configured to transmit the compressed data in a first frequency band, and transmit the compensation value data in a second frequency band different from the first frequency band.

Still further illustrative aspects are directed to a method, comprising receiving a first transmission in a first frequency band, the first transmission representing compressed data; receiving a second transmission in a second frequency band different from the first frequency band, the second transmission representing compensation value data; decompressing at least a portion of the compressed data using at least some of the compensation value data to generate decompressed data; and displaying the least a portion of the decompressed data as video on a display device.

Yet further illustrative aspects are directed to an apparatus, comprising a receiver and a decompressor. The receiver may be configured to receive a first transmission in a first frequency band, the first transmission representing compressed data, and receive a second transmission in a second frequency

band different from the first frequency band, the second transmission representing compensation values. The decompressor may be configured to decompress at least a portion of the compressed data using at least some of the compensation values to generate decompressed data.

These and other aspects of the disclosure will be apparent upon consideration of the following detailed description.

#### BRIEF DESCRIPTION OF THE DRAWINGS

A more complete understanding of the present disclosure and the potential advantages of various aspects described herein may be acquired by referring to the following description in consideration of the accompanying drawings, in which like reference numbers indicate like features, and wherein:

FIG. 1 is a functional block diagram of an illustrative system for transferring compressed data to one or more customers;

FIG. 2 is a functional block diagram of an illustrative computer that may be used to implement one or more elements of the system of FIG. 1;

FIG. 3 graphically shows illustrative QAM bandwidth regions in which the compressed data may be transferred;

FIG. 4 is a graph showing illustrative utilized bandwidth over time within one of the bandwidth regions of FIG. 3;

FIG. 5 is a flowchart of an illustrative process that may be performed by the system of

FIG. 1 to transfer the compressed data to the one or more customers;

FIG. 6 is a graph showing illustrative utilized bandwidth over time within one of the frequency bands of FIG. 3 used as a compensation frequency band (e.g., compensation QAM); and

FIG. 7 is a flowchart of an illustrative process that may be performed by one or more of the clients of FIG. 1 to decompress the received compressed data utilizing compensation values.

#### DETAILED DESCRIPTION

FIG. 1 is a functional block diagram of an illustrative system (such as a cable, fiber optic, satellite, or hybrid television program provider system) for transferring compressed data to one or more viewers or other clients. The system in this example includes a content/data source **101**, a compressor **102**, an edge QAM **103**, a network **104**, a first client represented by customer premises equipment (CPE) **105** and a second client represented by CPE **106**. Each of CPE **105**, **106** may include or be coupled to a display device **107**, **108**, such as a television display or computer display. Although each functional block **101-106** is shown as a single element in FIG. 1, it is to be understood that any of the functional blocks **101-106** may be implemented as one or more physical units. Each of the functional blocks **101-106** will now be discussed in turn.

Content/data source **101** may generate or otherwise provide data to be compressed by the system. The data may represent, for example, audio and/or video content (such as a television show or a movie) that may or may not already be compressed such as by MPEG compression. However, the data may be any arbitrary type of data that is desired to be transferred to CPE **105** and/or CPE **106**.

Compressor **102** compresses the data received from content/data source **101** using any type of compression desired. For example, compressor **102** may compress the data into one or more transport streams, such as MPEG transport streams. Compressor **102** may be or otherwise include an MPEG

groomer. Where the data from content/data source **101** is already compressed, the compression performed by compressor **102** may be recompression. In general, the terms “compression,” “compress,” or “compressed” as used herein refers to both initial compression and any subsequent recompression, unless otherwise specified.

Compressor **102** may determine whether compression is needed, and/or the amount and/or type of compression to be used, based on the bandwidth of the data received from content/data source **101**. The determination may depend upon whether the content data destined for one or more content QAMs will fit within those content QAMs. In other words, for each content QAM in which the associated content data bandwidth is determined to exceed the bandwidth of that content QAM, compressor **102** may compress (which includes initial compression or recompression after initial compression) the content data so as to fit within that content QAM. Compressor **102** may also generate compensation values based on that compression. Data representing the compressed content data and the compensation values are then fed to edge QAM **103** for distribution to customers. Compressor **102** may further compress the compensation value data if desired.

Edge QAM **103** in turn modulates the received compressed data and compensation value data, modulates the compressed data and/or compensation value data into one or more content QAMs and/or compensation QAMs, and forwards the content and/or compensation QAMs to CPE **105** and **106** (and/or other CPEs) via network **104**. Edge QAM **103** may include a transmitter as network input/output interface **204** (FIG. 2) that is capable of simultaneously transmitting to network **104** the content QAM(s) and/or the compensation QAM(s).

Network **104** may be any type of network or combination of networks, such as but not limited to the Internet, a dedicated cable, fiber optic, satellite, or hybrid television distribution network, a wireless cellular network, and/or a local area network. Network **104** may be configured so as to have sufficient capacity to provide the modulated content and/or compensation QAMs in near real time.

CPE **105** and **106** may each be or otherwise include any type of device or system for receiving, processing, decompressing, and rendering the content data on the content QAMs. CPE **105** and **106** may further be capable of receiving and utilizing the compensation values during decompression. In the present example, each of CPE **105** and **106** includes a decompressor **109**, **110**, and two tuners arbitrarily named Tuner A and Tuner B. These tuners may be physically implemented separately (e.g., two separate sets of tuner circuitry) and/or may be physically implemented as a single tuner with multiple simultaneous tuning capability (e.g., a single physical tuner implementing two logical tuners). In either case, CPE **105** and **106** may each be configured to be capable of simultaneously receiving and tuning to more than one channel in one or more content QAMs and/or compensation QAMs. Thus, for example, CPE **105** and **106** may each be capable of tuning not only to a particular content PID in a particular content QAM, but also simultaneously to a particular PID in a compensation QAM containing the compensation value data. Many conventional CPE devices already contain multi-tuning capability, such as set top boxes and television sets having picture-in-picture (PiP) functionality. In such a case, Tuner A may be the standard tuner and Tuner B may be the PiP tuner, or vice-versa. Tuners A and B may also include receivers for receiving all data from network **104**. Decompressors **109**, **110** may be implemented as dedicated hardware decompressors, and/or as software decompressors. For instance, decompressors **109**, **110** may be implemented by functions performed by processor **201** (FIG. 2).

5

All of functional blocks **101**, **102**, **103**, **105**, and **106** each may be implemented as, or otherwise include, one or more computers. The term "computer" as referred to herein broadly refers to any electronic, electro-optical, and/or mechanical device, or system of multiple such devices, that is able to process and manipulate analog and/or digital information, such as in the form of data. Non-limiting examples of a computer include one or more personal computers (e.g., desktop or laptop), servers, cellular phones, personal digital assistants (PDAs), television set top boxes, and/or a system of these in any combination or subcombination. In addition, a given computer may be physically located completely in one location or may be distributed amongst a plurality of locations (i.e., may implement distributive computing). A computer may be or include a general-purpose computer programmable to implement a wide variety of functions, and/or a dedicated computer that is configured to perform only certain limited functions.

An example functional-block representation of a computer **200** is shown in FIG. 2, from which any of blocks **101**, **102**, **103**, **105**, and **106** may be implemented. Computer **200** may include hardware that may execute software and/or be configured in hardware to perform specific functions. The software may be stored on a computer-readable medium **202** in the form of computer-readable instructions. Computer **200** may read those computer-readable instructions, and in response perform various steps as defined by those computer-readable instructions. Thus, any functions attributed to blocks **101**, **102**, **103**, **105**, and **106** as described herein may be implemented, for example, by reading and executing such computer-readable instructions for performing those functions, and/or by any hardware subsystem (e.g., a processor **201**) from which computer **200** is composed.

The term "computer-readable medium" as used herein includes not only a single physical medium or single type of medium, but also a combination of one or more physical media and/or types of media. Examples of a computer-readable medium include, but are not limited to, one or more memory chips, hard drives, optical discs (such as CDs or DVDs), magnetic discs, flash drives, and magnetic tape drives.

Such a computer-readable medium **202** may store computer-readable instructions (e.g., software) and/or computer-readable data (e.g., information that may or may not be executable). In the present example, computer-readable medium **202** (such as memory) may store computer-executable instructions and/or data used by any of blocks **101**, **102**, **103**, **105**, **106**. Alternatively or additionally, such a computer-readable medium **202** storing the data and/or software may be physically separate from, yet accessible by, blocks **101**, **102**, **103**, **105**, **106**.

Computer **200** also includes a user input/output interface **203** for receiving input from a user (e.g., via a keyboard, mouse, and/or remote control) and providing output to the user (e.g., via display device **107** or **108**, an audio speaker, and/or a printer). Computer **200** further includes a network input/output interface **204** for communicating with a network such as network **104**, and/or for communicating with external devices directly. Thus, any communication between blocks **101**, **102**, **103**, **105**, and **106** and users, network **104**, and each other may be attributed to communication via user input/output interface **203** and/or network input/output interface **204** of those respective blocks.

FIG. 3 graphically shows illustrative QAM bandwidth regions QAM-1, QAM-2, QAM-3, and QAM-4, in which the compressed data may be transferred over network **104**. The QAM bandwidth regions may be content QAMs and/or com-

6

pensation QAMs. For example, QAM-1, QAM-2, and QAM-3 may each be a content QAM containing multiple content channels, and QAM-4 may be a compensation QAM. While QAM-1, QAM-2, QAM-3, and QAM-4 are each illustratively shown as a single continuous frequency band, one or more of QAM-1, QAM-2, QAM-3, and QAM-4 may each be composed of multiple discontinuous frequency bands. Also, while a compensation QAM such as QAM-4 may be a dedicated compensation QAM, the compensation value data therein may share bandwidth with other data, such as in the same QAM that transfers data, such as DOCSIS (Data Over Cable Service Interface Specification) data. Also, while QAM-1, QAM-2, QAM-3, and QAM-4 are each illustratively shown as frequency bands that do not overlap each other in frequency, it is possible that one or more of these frequency bands may overlap in frequency.

FIG. 4 is a graph showing illustrative utilized bandwidth over time within one of the bandwidth regions of FIG. 3, such as QAM-1. In this example, content QAM-1 includes twelve channels (arbitrarily numbered 1-12), and has a maximum fixed bandwidth capacity of 38.81 Mbit/sec (which is the standard maximum capacity for a 256-QAM modulated 6 MHz wide QAM bandwidth region). While much of the time the total utilized bandwidth is less than the maximum bandwidth capacity, in a few instances (e.g., at about time=2, time=4, and time=10) the total utilized bandwidth for channels 1-12 equals or approaches 38.81 Mbit/sec. Thus, at and/or around those identified times, compressor **102** may identify this situation, and in response compress the data for one or more of channels 1-12 such that the total bandwidth of channels 1-12 is equal to or less than 38.81 Mbit/sec, as would be accomplished by a conventional MPEG grouper. In addition, compressor **102** would generate compensation values associated with the compression. Of course, other maximum bandwidths may be used, depending upon the configuration of the QAM bandwidth regions. For example, a QAM bandwidth region using 64-QAM modulation would normally have a maximum bandwidth capacity of 26.97 Mbit/sec.

FIG. 5 is a flowchart of an illustrative process that may be performed by the system of FIG. 1 to transfer the compressed data to the one or more customers. In step **501**, content data provided by content/data source **101** may be compressed (if not already compressed) by compressor **102** for modulation into one or more content QAMs. Compressor **102** may know the maximum allowable bandwidth of each content QAM, and may check to ensure that the total compressed bandwidth of the content for each QAM does not exceed the maximum allowable bandwidth (or does not exceed some other threshold bandwidth less than the maximum allowable bandwidth). In other words, for each set of channels destined for a given content QAM, compressor **102** may determine whether the content for that set of channels will fit within the associated content QAM (step **502**). If, for a given content QAM, the content will fit (such as occurs at times=5 through 9 in FIG. 4), then in step **505** the content as-is is formatted and modulated by edge QAM **103** into the content QAM, and in step **506** the content QAM is sent into network **104** for broadcasting, multicasting, unicasting, or other type of transmission to CPE **105** and/or **106**. Because multiple content QAMs are typically sent simultaneously with each other, the above process may be performed for all of those content QAMs.

If, however, the content for the set of channels is determined not to fit (such as might occur at time=2 in FIG. 4), then compressor **102** may compress, or further compress, the data for that content such that it will fit (step **503**). For example, compressor **102** may sufficiently compress the content of QAM-1 such that its bandwidth is no greater than 40 Mbit/

sec. The type and amount of compression may be altered as needed to ensure the utilized bandwidth is maintained within the established limit. As discussed previously, in many cases such compression may involve lossy compression because non-lossy compression would be insufficient to reduce the bandwidth below the established limit. In that case, compressor 102 may generate one or more compensation values in step 504 and forward those compensation values as data along with the compressed content to edge QAM 103. In turn, in steps 505 and 506, edge QAM 103 processes the compressed content as data packets, each identifying the channel PID, into a content QAM, and processes the compensation values as data packets, each identifying a compensation value PID, into a compensation QAM that utilizes bandwidth that may be different from the content QAM. It is noted that such lossy compression may be performed in addition to any earlier lossy or non-lossy compression already performed on the content. Thus, the determination of whether the content bandwidth exceeds the content QAM maximum bandwidth may be based on the bandwidth of the initially compressed content as received by compressor 102.

The compensation values may be values that identify the information lost during the lossy compression. For example, where the lossy compression loses higher resolution information (e.g., highly detailed image features), the compensation values may identify that higher resolution information. Any one or more features of the video and/or audio signal may be lowered in resolution in this lossy compression process. For example, the number of available colors may be reduced and/or the number of pixels in each video image frame may be reduced. Another way to compress the video may be to alter the compression quantization matrix to eliminate higher frequency components from the image.

In another example, encoding similar to JPEG 2000 progressive resolution encoding may be used for video encoding. For instance, each video frame may be considered a still image and individually encoded using JPEG 2000 or a similar encoding technique. In such a case, multiple layers for each video frame may be compressed, where the layers are ordered from most significant to least significant (in terms of the amount that each layer affects the video image). In this way, any overflow into the compensation QAM may start with the least significant layers, thereby affecting the video as little as possible in the event that the compensation value data is not utilized by the customer. Thus, in this example, the compensation values would be or otherwise represent those layers that were removed from the JPEG 2000 encoded frames being sent over the content QAM.

Regardless of the type of information lost during this compression, by separating out the compensation value data identifying the lost information, the original MPEG stream may be split between the content QAM and the compensation QAM such that the content QAM maximum bandwidth is not exceeded. Moreover, because the customer receives both the content QAM and the compensation QAM, the customer is able to reconstruct the MPEG stream using the compensation value data back to (or close to) its original information state prior to the lossy compression. In the alternative, the same QAM may contain both content and compensation value data for that content or for other content.

FIG. 6 is a graph showing illustrative utilized bandwidth over time within one of the frequency bands of FIG. 3 used as a compensation QAM, such as QAM-4. In this example, the compensation value data for content QAM-1, content QAM-2, and content QAM-3, are all transmitted on the same compensation QAM-4. For each content QAM, the corresponding compensation value data may be identified by a unique PID

identified in each compensation value data packet. As can be seen, the compensation value data may be expected to utilize significantly less bandwidth than the content to which the compensation value data corresponds. Accordingly, it may be expected that in many instances even a single compensation QAM having the same or a smaller maximum available bandwidth than a content QAM may still be able to accommodate the compensation value data for a plurality of such content QAMs. As can also be seen, at various times there are no compensation values at all for a given content QAM. These times correspond in this example to times when the content in the corresponding content QAM does not exceed the maximum available bandwidth for that content QAM.

FIG. 7 is a flowchart of an illustrative process that may be performed by CPE 105 and/or 106 of FIG. 1 to decompress the received compressed data utilizing received compensation value data. For purposes of explanation, it will be assumed that CPE 105 is performing the receiving and decompression. In step 701, CPE 105 uses Tuner A to select the desired PID of the desired channel. For example, Tuner A may select channel 2 in content QAM-1 of FIG. 4.

In step 702, CPE 105 may determine whether Tuner B (or some other tuner of CPE 105) is available. Tuner B may be unavailable for any reason, such as already being tuned to another channel being recorded to a digital video recorder. If Tuner B (or any tuner other than Tuner A) is unavailable, then decompression of the selected PID content may be performed in a conventional manner in step 703, and the resulting decompressed content may be rendered in step 704, such as by being displayed on display device 107.

If Tuner B (or any other tuner) is available, then in step 705 Tuner B selects the PID for the compensation value data that corresponds to the PID of the selected channel (in this example, the compensation value data that corresponds to content channel 2). To accomplish this, for example, CPE 105 may have stored in a computer-readable medium a table associating each channel and/or content QAM with a compensation value PID. An example of such a table is shown below in Table 1, using arbitrary PID values. Alternatively, there may be a known correspondence between content channel PIDs and compensation value PIDs, where the compensation value PID may be calculated from the content channel PID (such as by adding a constant value to the content channel PID). As yet another alternative, a low data-rate feed may be included in each content QAM (and thus received by CPE 105) that maps the PID of the content for each channel with the PID of the corresponding compensation value data. While in the example of Table 1 the PID of a channel is different from the PID of the related compensation value data, it is possible that the PID may be the same for both. The bandwidth used by the low data-rate feed may be taken into account when defining the remaining maximum bandwidth capacity of a content QAM available for channel content.

TABLE 1

Channel PID	Compensation Value PID
1	501
2	502
3	503
—	—
499	999

Then, in step 706, CPE 105 decompresses the compressed content data received by Tuner A using the associated compensation value data received by Tuner B, and the resulting decompressed content may be rendered in step 704. This

process of FIG. 7 may be repeated continuously while content is being received and rendered, and CPE 105 may dynamically switch between the 702-703-704 branch of the flowchart and the 702-705-706-704 branch of the flowchart, depending upon the availability of Tuner B at any given time. Such switching may be automatic and may be transparent to the user of CPE 105. Of course, where there is no compensation value data for the selected content channel, then step 706 may be performed without the benefit of the compensation value data.

In step 706, the compensation value data may be used in a manner suitable to the type of compensation values provided and/or the type of compression experienced by the content data. For example, where the compensation values represent lower-significance layers generated using the JPEG 2000 technique or a similar technique, then one or more of those layers may be represented by the compensation values and may be added back in to the content data for decompression.

Thus, techniques for providing compensation values of content QAMs containing content that has been compressed in a lossy manner have been described. While certain embodiments have been described herein, such embodiments are merely illustrative, and variations are possible while still remaining within the scope and spirit of the present disclosure. For example, while content and compression QAMs have been illustratively described as utilizing quadrature amplitude modulation, any other type of bandwidth regions with any other type of modulation may be utilized in place of the QAM bandwidth regions described herein. Moreover, while the content QAMs as described herein have a fixed maximum bandwidth, this is not necessary. A content QAM (or other type of bandwidth region) may have a variable maximum bandwidth even though the compensation values are provided to the customer outside of that content QAM bandwidth.

The invention claimed is:

1. A method, comprising:

transmitting, by at least one transmitter, a first plurality of data streams each in a respective frequency band, the first plurality of data streams each comprising a compressed version of content; and

transmitting a second plurality of data streams in a frequency band different from the respective frequency band of each of the first plurality of data streams, each of the second plurality of data streams comprising data corresponding to information lost from compression of the content of a respective one of the first plurality of data streams.

2. The method of claim 1, further comprising compressing, by at least one computing device, the content to generate the compressed version of the content.

3. The method of claim 1, further comprising compressing, by at least one computing device, at least one of the first plurality of data streams in response to a determination that transmission of data comprising the at least one of the first plurality of data streams would exceed a predetermined bandwidth.

4. The method of claim 1, wherein the transmitting the second plurality of data streams is performed at least partially simultaneously with the transmitting the first plurality of data streams.

5. The method of claim 1, wherein the transmitting the first plurality of data streams comprises transmitting a first data stream of the first plurality of data streams and a second data stream of the first plurality of data streams, the first data stream having a first program identifier (PID) and the second data stream having a different second PID.

6. The method of claim 5, wherein the transmitting the second plurality of data streams comprises transmitting a third data stream of the second plurality of data streams and a fourth data stream of the second plurality of data streams, the third data stream having a third PID and the fourth data stream having a fourth PID, wherein the first PID, the second PID, the third PID, and the fourth PID are all different.

7. The method of claim 6, further comprising determining the third PID based at least in part on the first PID.

8. The method of claim 6, further comprising determining the third PID by combining the first PID with a fixed value.

9. The method of claim 1, wherein the transmitting the first plurality of data streams and the transmitting the second plurality of data streams are performed by a plurality of transmitters comprising the at least one transmitter.

10. A method, comprising:

receiving, by a computing device:

a first plurality of data streams each in a respective frequency band, the first plurality of data streams comprising a compressed version of content; and

a second plurality of data streams in a frequency band different from the respective frequency band of each of the first plurality of data streams, the second plurality of data streams comprising data corresponding to information lost from a compression of the content; and

generating, by the computing device, a signal for display using at least one data stream of the first plurality of data streams and at least one data stream of the second plurality of data streams.

11. The method of claim 10, further comprising sending the signal to a display device.

12. The method of claim 10, wherein the generating the signal for display comprises modifying the at least one data stream of the first plurality of data streams using the at least one data stream of the second plurality of data streams.

13. The method of claim 10, wherein the receiving the first plurality of data streams comprises receiving a first data stream of the first plurality of data streams and a second data stream of the first plurality of data streams, the first data stream having a first program identifier (PID) and the second data stream having a different second PID.

14. The method of claim 13, wherein the receiving the second plurality of data streams comprises receiving a third data stream of the second plurality of data streams and a fourth data stream of the second plurality of data streams, the third data stream having a third PID and the fourth data stream having a fourth PID, wherein the first PID, the second PID, the third PID, and the fourth PID are all different.

15. The method of claim 14, further comprising:

selecting the first PID to tune the computing device to the first data stream;

determining the third PID based at least in part on the first PID; and

selecting the third PID to tune the computing device to the third PID,

wherein the generating the signal for display comprises generating the signal for display using the first data stream and the third data stream.

16. The method of claim 14, further comprising:

selecting the first PID to tune the computing device to the first data stream;

determining the third PID by combining the first PID with a fixed value; and

selecting the third PID to tune the computing device to the third PID,

wherein the generating the signal for display comprises generating the signal for display using the first data stream and the third data stream.

**17.** A method, comprising:

transmitting, by at least one transmitter, a first plurality of 5  
data streams each in a respective frequency band, the  
first plurality of data streams each comprising content of  
a first quality; and

transmitting a second plurality of data streams in a fre-  
quency band different from the respective frequency 10  
band of each of the first plurality of data streams, each of  
the second plurality of data streams comprising data  
that, in combination with a respective one of the first  
plurality of data streams, represents content of a second  
quality higher than the first quality. 15

**18.** The method of claim **17**, wherein the first quality comprises a first resolution and the second quality comprises a second higher resolution.

**19.** The method of claim **17**, wherein the transmitting the second plurality of data streams is performed at least partially 20  
simultaneously with the transmitting the first plurality of data streams.

**20.** The method of claim **17**, further comprising generating, 25  
for at least one of the first plurality of data streams, the content  
of the first quality by using compression.
